ABSTRACT

Krüppel-like factor 4 (KLF4), a transcription factor involved in both tumor suppression and oncogenesis in various human tumors, is subject to alternative splicing that produces KLF4 α . KLF4 α is primarily expressed in the cytoplasm because it lacks exon 3 of KLF4, which contains the nuclear localization signal. The role of KLF4 in breast cancer remains unclear and nothing is known yet about the expression and function of the isoform KLF4 α . Here, we show that KLF4 α is expressed in normal and tumoral tissue of the breast and provide evidence that the KLF4 α /KLF4(full-length) (FL) ratio is increased in tumors compared to corresponding normal tissue. Forced increase of the KLF4 α /KLF4(FL) ratio in the metastatic breast cancer cell line MDA-MB-231 decreases the levels of *E-Cadherin*, *p21^{Cip1}*, and *p27^{Kip1}*, three known KLF4(FL) target genes, and stimulates cell proliferation. We suggest that cytoplasmic KLF4 α binds to KLF4(FL) and retains it in the cytoplasm thereby antagonizing the gene regulatory activities of KLF4(FL) in the nucleus. Our results establish KLF4 α as a KLF4 isoform that opposes the function of KLF4(FL) and as an important factor in the complex and unresolved role of KLF4(FL) in breast carcinogenesis.

INTRODUCTION

Krüppel-like factors (KLFs) comprise a highly conserved transcription factor family of 17 members [1]. They are known to regulate cellular functions such as proliferation, apoptosis, migration, differentiation, and pluripotency [2–4]. KLF4 is the best-studied member of the family and it is one of the factors in the “Yamanaka cocktail”, which upon transfection, allows the conversion of adult cells into induced pluripotent stem cells [5].

KLF4 has been extensively studied in the context of tumors and current data suggest that it can either act as tissue-specific tumor-inhibiting or -promoting gene with the underlying mechanism remaining unclear [6, 7]. KLF4 has been reported to have tumor-suppressive functions in various tumors, including tumors of the colon, bladder, prostate, and stomach [8–13], while it acts as a pro-tumorigenic gene in oral and skin squamous cell carcinomas [14, 15].

The role of KLF4 in breast cancer remains less clear and contradictory data exist. It is believed that KLF4 is

expressed at low levels in normal breast epithelium, but over-expressed during breast tumor progression [16]. Furthermore, increased nuclear KLF4 expression is considered to be a marker of an aggressive phenotype in early-stage infiltrating ductal carcinoma [17]. Additionally, KLF4 plays a prominent role in the maintenance of the cancer stem cell-like population, which promotes cell migration and invasion [18]. However, the role of KLF4 as a putative tumor-promoting gene in breast cancer remains unresolved: extensive analyses of the Oncomine database revealed lower KLF4 mRNA levels in breast tumor tissues, compared with normal tissues, in 9 of 11 data sets and indicated that the levels are inversely correlated with tumor grade [19]. Moreover, two new genetic variants in the estrogen-receptor positive breast cancer susceptibility locus 9q31.2 [20] have been recently identified that target KLF4 via long-range chromatin interactions [21]. These data show that lower levels of KLF4 are associated with increased breast cancer risk and promote KLF4 as a tumor suppressor-like gene [20, 21]. Similarly, KLF4 inhibits epithelial-mesenchymal-transition (EMT) and metastasis

in breast cancer models [22–24]. Thus, KLF4's role in breast tumors remains a conundrum.

Only recently, KLF4 isoforms have been identified [25–27]. One of the main KLF4 isoforms, KLF4 α , has been shown to be over-expressed in pancreatic cancers and to correlate with the aggressiveness of tumors and poor patient prognosis [26].

Here, we aimed to elucidate whether KLF4 α is expressed in breast cancer cells and, if so, whether increased KLF4 α levels might explain some of the complexity of KLF4's role in breast tumorigenesis. We have established that KLF4 α is expressed in the cytoplasm of breast cancer cells and present evidence that an increased KLF4 α /KLF4(FL) ratio is often found in tumors compared to normal tissue. Our data suggest that KLF4 α acts as a dominant KLF4(FL) antagonist and prevents nuclear translocation of KLF4(FL), thereby altering the transcriptional landscape in breast cancer cells. We provide evidence that KLF4 α has tumor-promoting functions and that its expression may play a significant role in KLF4's complex functions in breast cancer.

RESULTS

Detection of KLF4 α in human breast cancer cells

Unresolved data on the role of KLF4 during breast carcinogenesis [4], as well as the identification of KLF4 α , a KLF4 isoform, as a tumor-promoting gene in pancreatic cancer [26], prompted us to study KLF4 α expression in breast cancer cells. To test whether normal and/or breast cancer cells express KLF4 α , we used MCF10A and MDA-MB-231 cells and performed RT-PCR with primers flanking the KLF4 gene (Figure 1A, 1B). A product of ~1440 bp was amplified in both cell lines, while a ~440 bp amplicon was detectable in the metastatic MDA-MB-231 cells only (Figure 1A). Sequencing of these PCR products revealed KLF4(FL) (1440 bp band; UniProtKB-O43474; KLF4 isoform 2) and KLF4 α (440 bp; UniProtKB-O43474-5). KLF4 α is a KLF4 isoform that lacks exon3, leading to a frameshift in exon4 and to a premature Stop codon in exon5 (Figure 1B and Supplementary Figure S1). All three zinc finger domains of KLF4(FL) and its nuclear localization signal (NLS) are not present in KLF4 α .

Next, we wanted to quantitatively study RNA levels of the two KLF4 variants in a panel of breast cancer cell lines (MCF7, T47D, MDA-MB-175, and MDA-MB-231), the normal human breast cell line (MCF10A), and also in samples from patients with ductal carcinoma. Specificity of qPCR primers recognizing KLF4(FL) and KLF4 α , respectively, as well as primers that detect both KLF4 variants ("KLF4 all") (Supplementary Figure S2) allowed us to study breast cancer-associated KLF4 splicing in more detail. KLF4 all levels were variable in all our samples analyzed (Figure 1C, left). KLF4(FL) levels mostly

paralleled those of KLF4 all, with the exception of the carcinoma patient 1 (Figure 1C, right). In three out of the four breast cancer cell lines tested, KLF4 α RNA was readily detectable (Figure 1C bottom). Only T47D cells were negative for KLF4 α . KLF4 α was not detectable in the normal breast cell line MCF10A, which confirmed our RT-PCR (Figure 1A). The relative expression patterns of KLF4(FL) and KLF4 α in the cell lines were very similar. In the two patient samples, however, KLF4 α showed higher expression than in cell lines, which was in contrast to KLF4(FL). Since both KLF4 variants were detectable in most of the breast cancer samples, we wished to determine the KLF4 α /KLF4(FL) ratio in each sample. KLF4 α /KLF4(FL) ratios were variable across the samples, but highest in the carcinoma patients, which was due to their elevated KLF4 α (Figure 1D).

So far, there is only limited data on KLF4 α expression in cancer cell lines [25, 26]. Thus, we decided to screen an additional panel of 21 human cancer cell lines from various origins for the expression of KLF4 all, KLF4(FL), and KLF4 α (Supplementary Figure S3). This analysis demonstrated that KLF4 α transcripts are expressed in 84% of the cancer cell lines tested, (including breast cancer; Supplementary Table 1).

KLF4 α in human tumors

To extend this study and to analyze clinically relevant specimens, we used a TissueScan™ Cancer and Normal Tissue cDNA Array. This array consists of five breast, kidney, lung, and ovary cancer samples and one normal control for each tissue (Supplementary Figure S4). qPCR analysis showed that KLF4 α transcripts were detectable in all control tissues (Figure 2A, right). KLF4 α expression was two-fold higher in normal kidney, lung, and ovarian tissue compared to normal breast (data not shown). KLF4 α RNA was also prominently expressed in all the different tumor patients. Comparing the levels of KLF4 α in control and tumor samples, no consistent difference could be observed in kidney, lung, and ovarian tumor patients. Only in the five breast cancer patients KLF4 α was consistently and prominently over-expressed compared to control tissue (Figure 2A right). KLF4(FL) was detectable in all normal tissues as well (Figure 2A, left) with highest expression in ovarian tissue and lowest levels in breast tissue (data not shown). In ovarian tumors all patients displayed a prominent reduction of KLF4(FL) levels confirming literature on tumor-suppressive functions of KLF4 in ovarian cancer [28]. When we determined the ratio KLF4 α /KLF4(FL) in all these clinical samples, we noticed an appreciable increase of the ratio in 4/5 breast, 3/5 kidney, 3/5 lung, and 5/5 ovary cancer samples compared to their corresponding healthy tissues (Figure 2A bottom panels).

To further solidify our hypothesis of an increased KLF4 α /KLF4(FL) ratio in tumors, we used a matched

pair RNA sample from an invasive ductal carcinoma and adjacent normal tissue (Figure 2B). *KLF4* *all*, *KLF4(FL)* as well as *KLF4 α* RNA levels were all prominently reduced in the tumor sample compared to control. Still, a significant increase of the *KLF4 α /KLF4(FL)* ratio in the tumor could be determined (Figure 2B).

Cytoplasmic localization of KLF4 α

To study KLF4(FL) and KLF4 α function in breast cancer cells, we cloned both cDNAs into mammalian expression plasmids and transfected MDA-MB-231 cells. The KLF4 antibody used in this study was raised against a C-terminal peptide corresponding to human KLF4 aa 300–400 and therefore, only detected KLF4(FL) (~65 kDa). KLF4 α (~18 kDa) could be detected by its myc-tag as well as by the antibody anti-GN330 [26] (Figure 3A). *KLF4(FL)* contains a NLS in exon 3 (Figure 1B), which is responsible for its nuclear localization (Figure 3B). In contrast, KLF4 α , lacking exon3, was localized primarily in the cytoplasm of MDA-MB-231 cells (Figure 3B, right panel). Complementary localization of KLF4(FL) and KLF4 α was further confirmed by preparing cytoplasmic and nuclear protein extracts of transfected MDA-MB-231 cells (Figure 3C). KLF4 α expression was only detected in the cytoplasmic fraction, while the vast majority of KLF4(FL) was present in the nuclear fraction (Figure 3C), which confirmed our staining results.

Specificity of the anti-GN330 antibody for KLF4 α (Figure 3A) allowed us to analyze endogenous KLF4 α protein levels in our breast cancer cells. KLF4 α was detected in extracts of MDA-MB-175, MDA-MB-231, and 172 (mutated p53 showing high KLF4 α RNA levels (Supplementary Figure S3C)), but not in T47D and MCF10A cells (Figure 3D). These results confirmed our RNA analyses (Figure 1C), suggesting a good correlation between KLF4 α RNA and protein levels.

Effects of KLF4(FL) and KLF4 α in MDA-MB-231 cells

Reported tumor-suppressive effects of forced KLF4 expression include the induction of the epithelial cell-adhesion molecule E-Cadherin and the cell cycle inhibitors p21^{Cip1} and p27^{Kip1} via direct binding of KLF4 to the respective promoter elements [22, 29, 30]. In our panel of breast cancer cells we detected strong variation of endogenous E-Cadherin, p21^{Cip1}, and p27^{Kip1} RNA and protein levels. High *E-Cadherin*, p21^{Cip1}, and p27^{Kip1} levels mostly correlated with high expression of *KLF4(FL)* in the breast cancer cell lines (Figures 1C, 4A). MDA-MB-231 cells, which are believed to have undergone an EMT, hardly express any E-Cadherin and p21^{Cip1} (Figure 4A, 4B).

Forced expression of KLF4(FL) in the highly metastatic MDA-MB-231 cells robustly restored E-Cadherin RNA as well as protein expression (Figure 4C

left panel, D lane 3). Similarly, KLF4(FL) over-expression induced p21^{Cip1}, while it was not able to stimulate p27^{Kip1} expression in MDA-MB-231 cells (Figure 4C right panel, 4D). These results suggest that KLF4(FL) appears to enforce an epithelial phenotype and to induce growth arrest by increasing E-Cadherin and p21^{Cip1} levels, respectively. Indeed, KLF4(FL) over-expressing MDA-MB-231 cells display a more cobblestone-like, epithelial morphology and have growth disadvantages compared to control cells (data not shown). In contrast, an increased KLF4 α /KLF4(FL) ratio by forced KLF4 α expression in MDA-MB-231 cells was not able to either induce E-Cadherin or p21^{Cip1}, but it decreased p27^{Kip1} levels compared to control (Figure 4C, 4D). Comparable results were obtained in KLF4(FL) and KLF4 α over-expressing MCF7 cells (data not shown).

KLF4 α antagonizes KLF4(FL) function

Next, we wanted to know whether an increased KLF4 α /KLF4(FL) ratio, which we had identified in tumors, might have consequences for KLF4(FL) target genes. Therefore, we generated KLF4 α /KLF4(FL) imbalances and analyzed their effects on KLF4's ability to induce E-Cadherin and p21^{Cip1} in MDA-MB-231 cells. Co-transfection of different amounts of KLF4(FL) and KLF4 α , respectively, altered their individual protein levels in a dose-dependent manner, thereby changing the KLF4 α /KLF4(FL) ratios (Supplementary Figure S5 and Figure 5C). Increased KLF4 α /KLF4(FL) ratios abrogated KLF4(FL)-mediated induction of E-Cadherin and p21^{Cip1} (Figure 5A, 5B left panels, 5C). In contrast, similar ratios of KLF4(FL)/pCMV6 ratios were still capable of inducing both genes (Figure 5A, 5B right panels). Our data demonstrate that increased KLF4 α /KLF4(FL) ratios, either generated by reduction of KLF4(FL) or gain of KLF4 α , antagonizes KLF4(FL)-mediated induction of E-Cadherin and p21^{Cip1}.

KLF4 α interacts with KLF4(FL)

An antagonistic function of KLF4 α on KLF4(FL) suggests that there might be an interaction of the two proteins. We hypothesized that KLF4 α binds KLF4(FL) in the cytoplasm, thereby preventing its translocation into the nucleus. To study this possibility, we co-transfected MDA-MB-231 cells with a 1:1 ratio of either KLF4 α -myc/KLF4(FL) or KLF4(FL)-myc/pCMV6 and analyzed the cellular localization of KLF4(FL) by immunofluorescence (Figure 6A, 6B). KLF4(FL) was primarily localized in the nucleus in KLF4(FL)/pCMV6 transfected cells (Figure 6A). In contrast, presence of KLF4 α significantly disturbed the nuclear localization of KLF4(FL), as evidenced by cytoplasmic staining patterns (Figure 6B). Typical examples are shown in Figure 6B. In the bottom row of Figure 6B, one out of

three cells shows an exclusive nuclear staining (indicated by the dotted line) for KLF4(FL). This cell does not express KLF4 α , whereas the two other cells that express KLF4 α , have KLF4(FL) in the cytoplasm as well. These observations were confirmed by quantifying the three cells of Figure 6B bottom row by linescan plots (Figure 6C). We further quantified these findings in more than 100 transfected, KLF4 α -positive MDA-MB-231 cells. We determined a statistically significant difference in the percentage of cells with exclusively nuclear KLF4(FL) in KLF4(FL)/pCMV6 versus KLF4(FL)/KLF4 α transfected

cells (Figure 6D). These data let us speculate that KLF4 α sequesters KLF4(FL) in the cytoplasm and consequently, KLF4(FL) levels in the nucleus should be decreased in the presence of KLF4 α . To test this hypothesis, we co-transfected MDA-MB-231 cells with different KLF4 α /KLF4(FL) ratios and analyzed their nuclear fractions for the levels of KLF4(FL). A prominent decrease of nuclear KLF4(FL) was observed in the presence of KLF4 α compared to control (pCMV6) (Figure 6E). Finally, we assessed the possibility of a direct or indirect interaction between KLF4 α and KLF4(FL) in the cytoplasm of MDA-

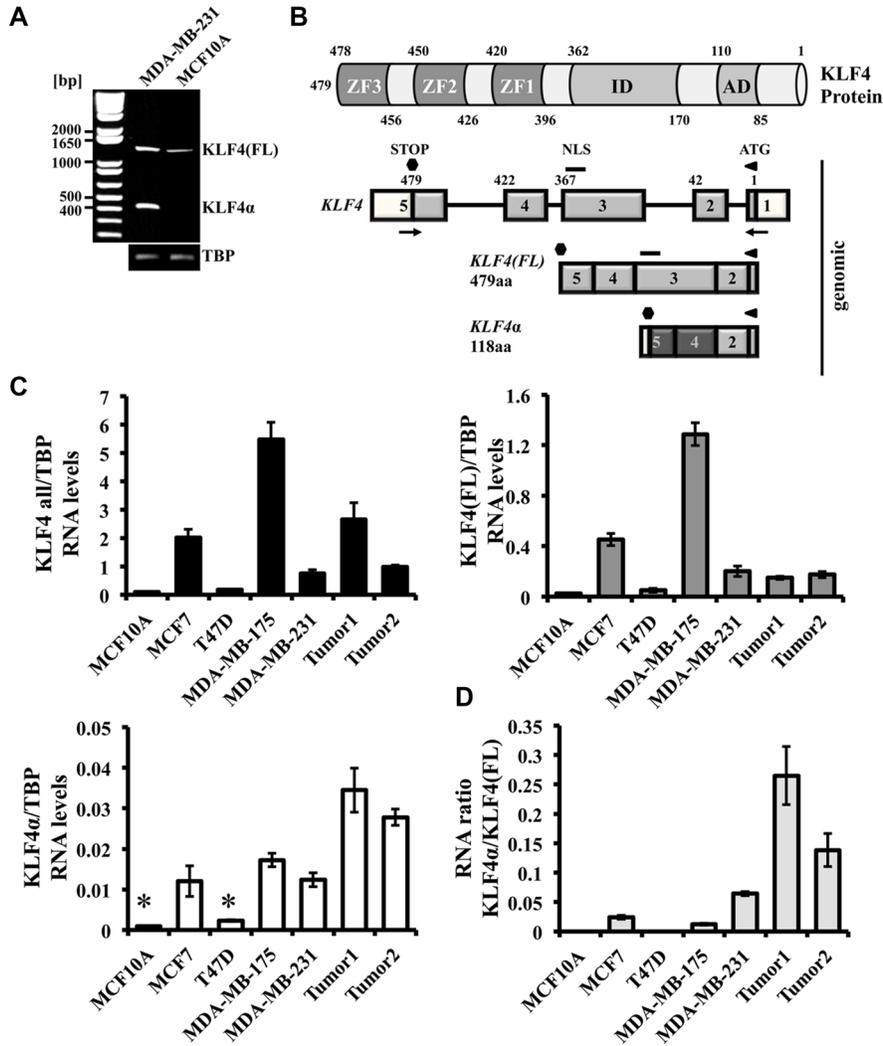

Figure 1: Detection of KLF4 α in human breast cancer cells. (A) RT-PCR analysis of *KLF4* in MDA-MB-231 and MCF10A cells. Both cell lines show the KLF4(FL) band (~1440 bp), whereas the KLF4 α band (~440 bp) is only detectable in MDA-MB-231 cells. (B) Schematic representation of the KLF4 protein structure (top) and the *KLF4* gene and its variants in MDA-MB-231 cells (bottom). The *KLF4* gene is located on chromosome 9 (reverse strand), contains 5 exons, which gives rise to a KLF4(FL) protein of 479aa. Skipping of exon3 produces KLF4 α (118aa). Numbers indicate the amino acids. AD: activation domain; ID: inhibitory domain; ZF: zinc fingers; NLS: nuclear localization signal; aa: amino acids; white boxes: untranslated exons; light grey boxes: shared sequence between KLF4(FL) and KLF4 α ; dark grey boxes: novel sequence in KLF4 α ; arrows: primers used in A). (C) qPCR analysis of a normal human breast cell line (MCF10A) compared to four human breast cancer cell lines and two human ductal breast carcinoma patients for the genes *KLF4 all*, *KLF4(FL)*, and *KLF4 α* . Note that *KLF4 α* is detectable in three out of the four breast cancer cell lines and that the two breast cancer patient samples show high levels of *KLF4 α* compared to cells. Data are expressed as the mean \pm SEM. $n = 3$. TBP: TATA-Box binding protein. * C_T values ≥ 34 . (D) RNA ratio of *KLF4 α* /*KLF4(FL)* indicates highest ratio in the two cancer patient samples.

MB-231 cells by co-IP experiments. Indeed, KLF4 α and KLF4(FL) associate with each other as evidenced by the appearance of a KLF4(FL) band in the KLF4 α -myc-immunoprecipitated sample (Figure 6F).

KLF4 α stimulates breast cancer cell proliferation

Finally, we wanted to learn more about the functional consequences of increased KLF4 α /KLF4(FL) ratios in MDA-MB-231 cells. First, we analyzed the actin cytoskeleton of KLF4 α -over-expressing MDA-MB-231 cells compared to control. While the control cells showed high actin expression throughout the cells, we noticed prominent cortical actin and mostly absence of intracellular actin in the KLF4 α -cells, which also

seemed to be larger than controls (Figure 7A). Since distinct actin network patterns might reflect changes in cellular motility, we wanted to check whether KLF4 α stimulates cancer cell migration. Boyden chamber assays as well as scratch wounds were performed and analyzed, but no significant difference in the migratory behavior of KLF4 α over-expressing MDA-MB-231 cells compared to control was observed (data not shown). Finally, we tested the role of altered KLF4 α /KLF4(FL) ratios on cell growth. While forced KLF4 α expression in the normal mammary cell line MCF10A did not change proliferation, the growth rate of T47D and MDA-MB-231 was increased upon KLF4 α over-expression (Figure 7B). Hence, KLF4 α only had a growth-promoting effect on breast cancer cell lines, which was independent of their respective endogenous total KLF4

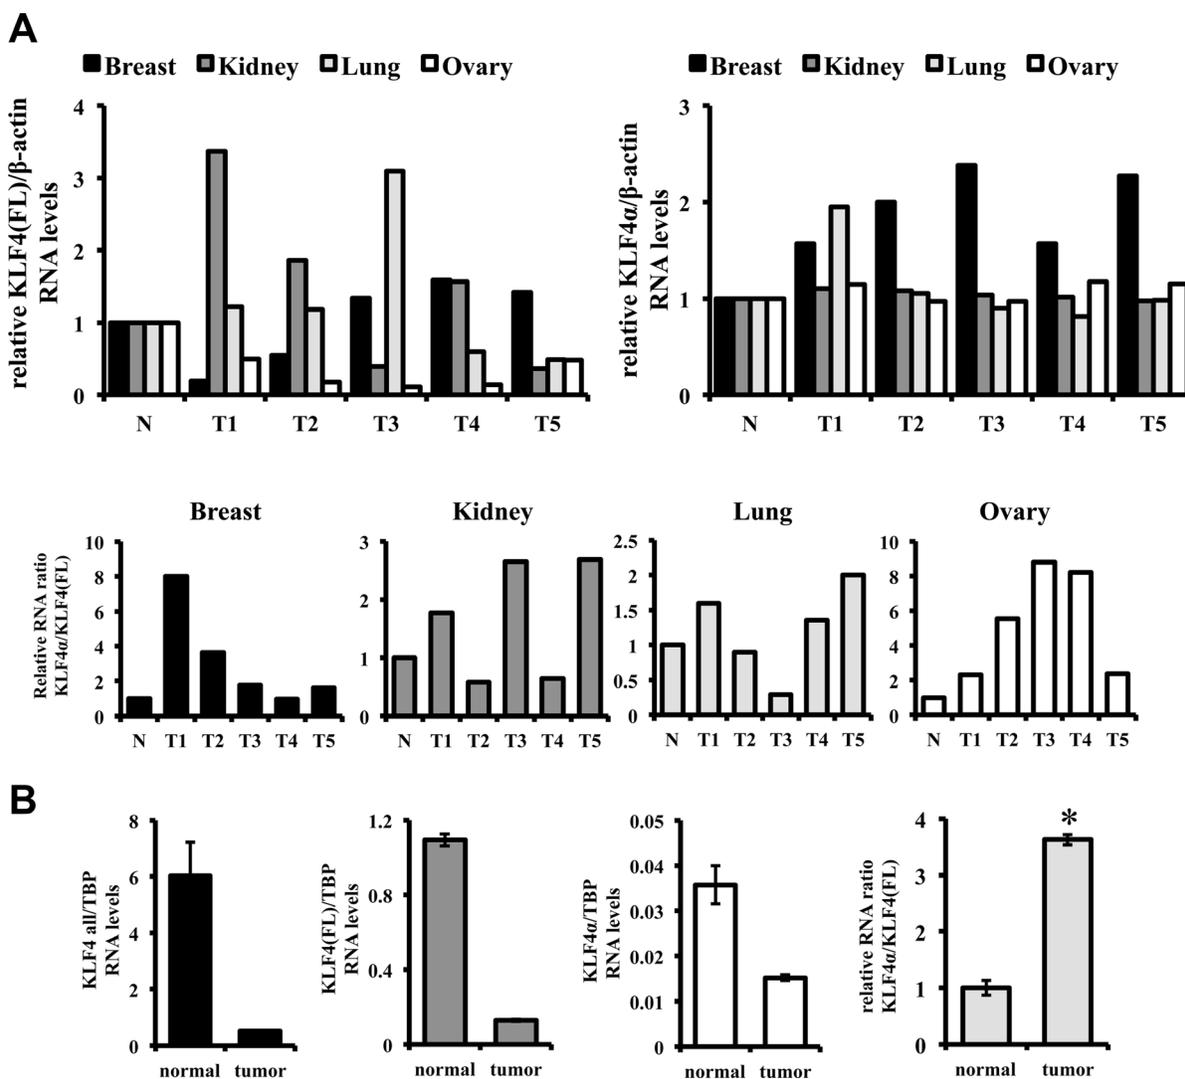

Figure 2: KLF4 α /KLF4(FL) imbalance in tumors. (A) qPCR analysis for KLF4(FL) and KLF4 α in TissueScans containing 5 different tumor samples (T1-5) and a normal control tissue (N). Consistent increases of KLF4 α /KLF4(FL) are detected in 4/5 breast, 3/5 kidney, 3/5 lung, and 5/5 ovary cancer samples compared to controls. (B) A matched pair of a ductal carcinoma breast patient was analyzed by qPCR for KLF4(FL) and KLF4 α . While KLF4 α , KLF4(FL) and KLF4 α RNA levels are decreased in tumors, there is a prominent KLF4 α /KLF4(FL) ratio imbalance in the tumor sample compared to the control tissue. TBP: TATA-Box binding protein. Data are expressed as the mean \pm SEM. $n = 3$. * $p \leq 0.05$ (tumor versus normal).

levels (low in T47D, high in MDA-MB-231) (Figure 1C). BrdU incorporation assays further demonstrated that increased KLF4 α /KLF4(FL) ratios by forced KLF4 α expression increased the fraction of cells within S phase (Figure 7B, bottom right). Thus, we propose KLF4 α as a novel, so far neglected oncogenic factor, which clarifies the role of KLF4 in breast cancer.

DISCUSSION

It is well established that KLF4 has ambiguous roles in human breast cancer. The general discovery of KLF4 variants [25–27] and our data on KLF4 α as an antagonist of KLF4(FL) in breast cancer might shed new light on the role of KLF4 during breast tumorigenesis.

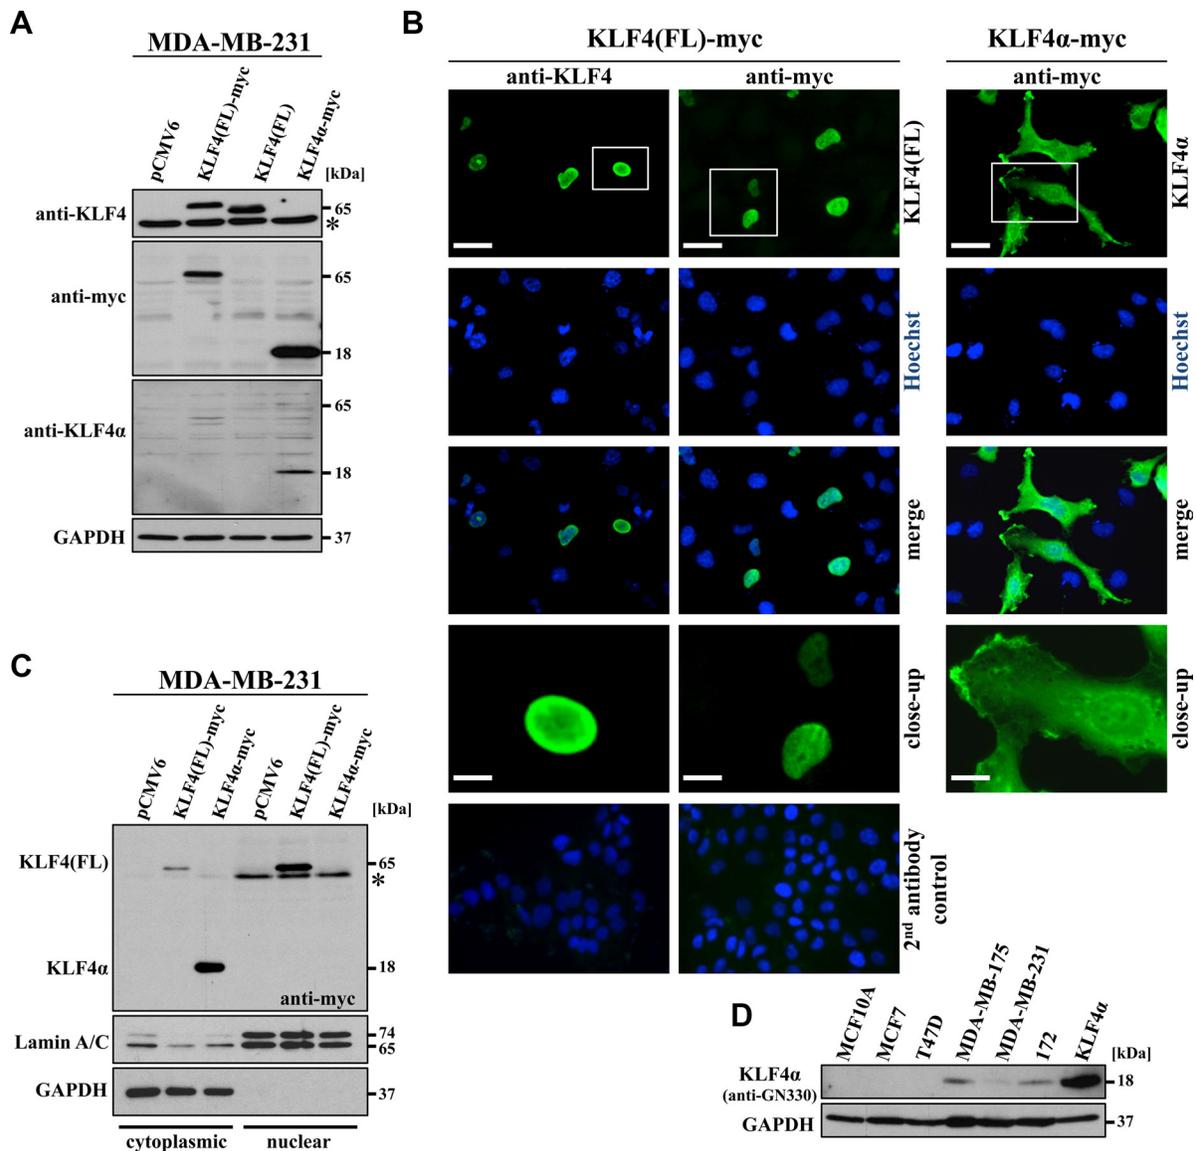

Figure 3: Characterization of KLF4 α expression. (A) MDA-MB-231 cells were transfected with the indicated plasmids and immunoblotted with α -KLF4, which only detects KLF4(FL), with α -myc, which detects both myc-tagged variants of KLF4, and with α -GN330, which specifically recognizes KLF4 α . *background band. (B) Immunofluorescent stainings of transfected MDA-MB-231 cells 24 h post-transfection show nuclear staining for KLF4(FL) and cytoplasmic staining for KLF4 α . Hoechst stain was used for the visualization of nuclei. Scale bar: 50 μ m (top); 10 μ m (close-up). The bottom row indicates the secondary antibody only controls merged with the respective Hoechst staining (left side: goat-anti-rabbit IgG-FITC; right side: goat-anti-mouse IgG-FITC). (C) Transfected MDA-MB-231 cells were extracted for the cytoplasmic and the nuclear fractions 36 hours after transfection and immunoblotted. KLF4 α is only found in the cytoplasmic, GAPDH-positive fraction, whereas most of KLF4(FL) is present in the nuclear, LaminA/C-positive fraction. * background band. (D) Western blot analysis of protein extracts of the normal breast cell line (MCF10A), four breast cancer cell lines as well as a p53-mutant Li Fraumeni cell line (172) in comparison to KLF4 α -transfected MDA-MB-231 cells for KLF4 α levels. Note that endogenous KLF4 α (~18kDa) is detectable in MDA-MB-175, MDA-MB-231, and 172 cells. GAPDH: glyceraldehyde-3-phosphate dehydrogenase.

In the current study, we analyzed the expression and function of the main KLF4 isoform, KLF4 α , in breast cancer cells. We demonstrate that KLF4 α is expressed in breast cancer cells and show that KLF4 α is primarily localized in the cytoplasm. Strong evidence is presented that KLF4 α sequesters KLF4(FL) in the cytoplasm through an association of KLF4 α with KLF4(FL). Consequently,

direct or indirect binding of cytoplasmic KLF4 α to KLF4(FL) prevents KLF4(FL) from nuclear translocation and results in altered transcriptional regulation of KLF4(FL) target genes, such as *E-Cadherin*, *p21^{Cip1}*, and *p27^{Kip1}*. Chromatin IP's have shown physical interaction of KLF4(FL) with the promoter of all three genes and KLF4-binding sites have been identified suggesting that

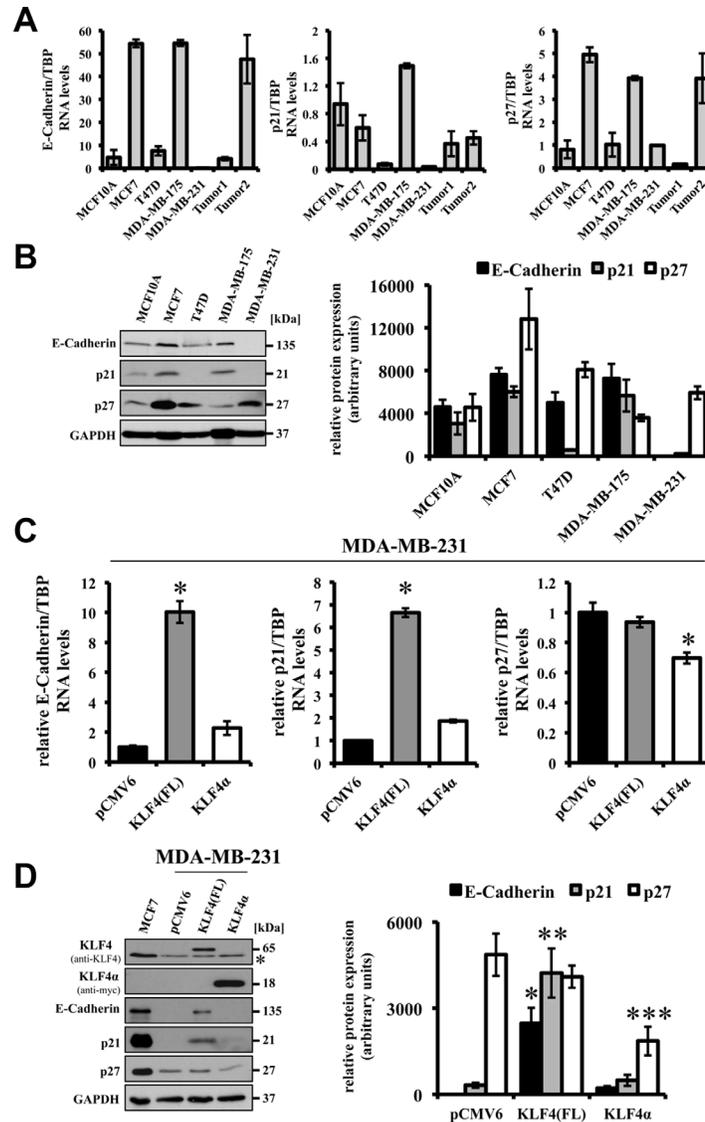

Figure 4: Effects of forced expression of KLF4(FL) and KLF4 α in MDA-MB-231 cells. (A) qPCR analysis of a normal human breast cell line (MCF10A) compared to 4 human breast cancer cell lines and two human ductal breast carcinoma patients for endogenous levels of *E-Cadherin*, *p21^{Cip1}* and, *p27^{Kip1}* shows various expression levels in the different samples. Note that *E-Cadherin* and *p21^{Cip1}* levels are very low in MDA-MB-231. Data are expressed as the mean \pm SEM. $n = 3$. (B) Western Blot analysis of the normal and cancerous breast cells for *E-Cadherin*, *p21^{Cip1}*, *p27^{Kip1}* indicates that protein levels correlate with RNA levels. Normalized protein levels of three independent western blots have been quantified and plotted. (C) Forced expression of KLF4(FL) in MDA-MB-231 cells induces *E-Cadherin* as well as *p21^{Cip1}* RNA, but not *p27^{Kip1}*. In contrast, forced expression of KLF4 α does neither affect basal levels of *E-Cadherin* nor *p21^{Cip1}*, but decreases *p27^{Kip1}*. Data are expressed as the mean \pm SEM. $n = 3$. TBP: TATA-Box binding protein. * $p \leq 0.05$ (KLF4(FL) versus pCMV6/KLF4 α). (D) Response of *E-Cadherin*, *p21^{Cip1}*, and *p27^{Kip1}* protein levels upon forced expression of KLF4(FL) and KLF4 α , respectively, in MDA-MB-231 cells in comparison to the endogenous protein levels in MCF7. Normalized protein levels of three independent western blots have been quantified and plotted. * $p \leq 0.05$ *E-Cadherin* in KLF4(FL) versus KLF4 α cells; ** $p \leq 0.05$ *p21^{Cip1}* in KLF4(FL) versus KLF4 α cells; *** $p \leq 0.05$ *p27^{Kip1}* in KLF4 α versus KLF4(FL) cells. Note that KLF4 α antagonizes KLF4(FL)-mediated target gene regulation and decrease *p27^{Kip1}*. GAPDH, glyceraldehyde-3-phosphate dehydrogenase. *background band.

KLF4(FL) transactivates E-Cadherin, p21^{Cip1}, and p27^{Kip1} [22, 29, 30]. We confirmed the ability of KLF4 to induce levels of E-Cadherin and p21^{Cip1} in the highly metastatic breast cancer cell line MDA-MB-231, but did not observe an increase of p27^{Kip1} upon forced KLF4 expression. However, increasing the KLF4 α /KLF4(FL) ratio in MDA-MB-231 strongly antagonized the effect of KLF4(FL) and decreased levels of E-Cadherin, p21^{Cip1}, as well as p27^{Kip1}. Augmented KLF4 α /KLF4(FL) ratios increased the fraction of cells within S phase and promoted a pro-tumorigenic phenotype by opposing the tumor-suppressive functions of KLF4(FL). Since we detected *KLF4 α* in human cancers of various origin, we speculate that our findings in breast cancer may be relevant for other tumors as well.

An antagonistic effect of KLF4 α on KLF4(FL) function can be explained by two potential mechanisms: Either there is an interaction of KLF4 α with KLF4(FL) in the cytoplasm, which then retains KLF4(FL) in the cytoplasm and inhibits nuclear translocation of KLF4(FL), or KLF4 α sequesters important co-factors in the cytoplasm required for KLF4(FL)-mediated gene regulation in the

nucleus. We cannot exclude the latter, but we showed that KLF4 α is associated with KLF4(FL) in the cytoplasm and that nuclear KLF4(FL) levels are decreased in the presence of KLF4 α compared to control cells. There is no evidence in the literature that KLF4 can form dimers. Therefore, the detailed molecular mechanism how KLF4 α associates with KLF4(FL) remains to be elucidated. It is plausible to speculate that alternative splicing produces novel motifs in KLF4 α that are responsible for the interaction or association with KLF4(FL). However, we did not identify any obvious structural motifs in KLF4 α .

Similar to our study on KLF4, it has been shown that splicing deregulation of KLF6 results in a specific variant, KLF6-v1, that is associated with an increased risk of various cancers and opposes KLF6(FL) effects [31–37]. It is believed that intronic and/or exonic site mutations and splicing factor alterations are the main reasons for aberrant splicing to occur in tumors [38]. We do not have any data on mutations affecting KLF4 splicing or splicing factor level alterations in human tumors. In the case of KLF6, it has been shown that a single germline DNA polymorphism is responsible for the generation of

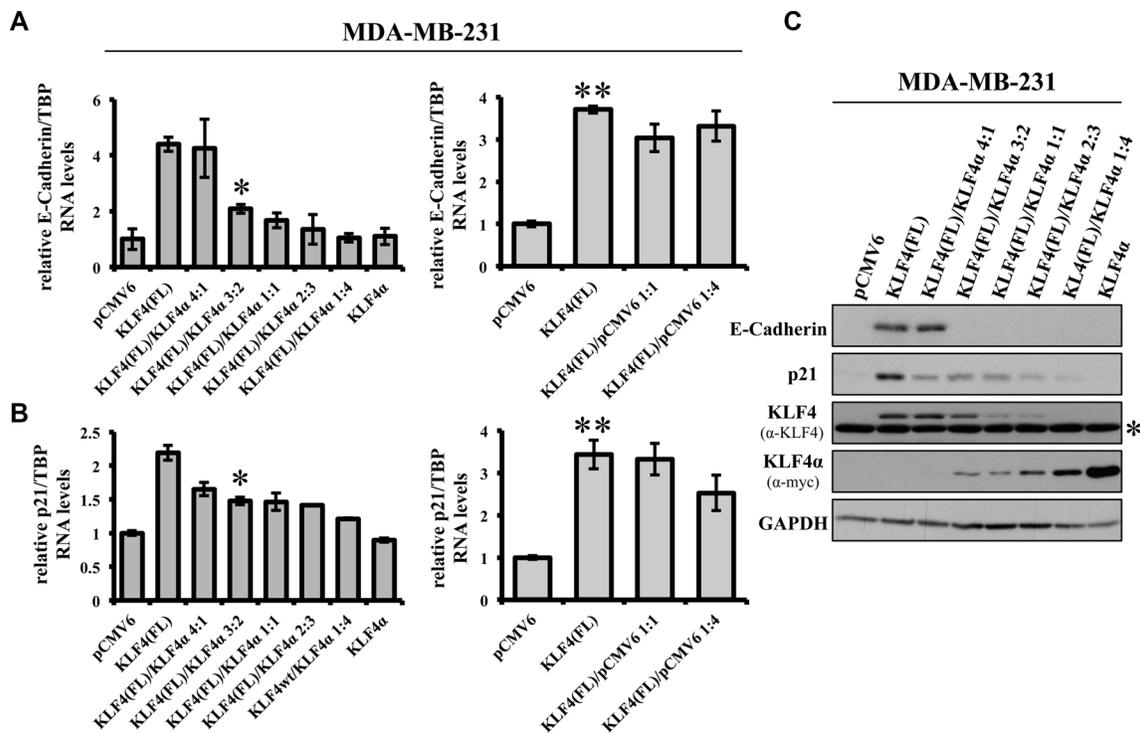

Figure 5: KLF4 α antagonizes KLF4(FL)-mediated effects on E-Cadherin and p21. (A) MDA-MB-231 cells were transiently transfected with different ratios of KLF4 α and KLF4(FL) followed by qPCR analysis for *E-Cadherin*. Increasing amounts of KLF4 α block KLF4(FL)-mediated *E-Cadherin* RNA induction (left panel). As a control, different ratios KLF4(FL)/pCMV6 were used followed by qPCR for *E-Cadherin* levels. Note that even KLF4(FL)/pCMV6 ratio of 1:4 still robustly induced *E-Cadherin* (right panel). Data are expressed as the mean \pm SEM. $n = 3$. * $p \leq 0.05$ (KLF4(FL) versus (FL)/ α 3:2). ** $p \leq 0.05$ (KLF4(FL) versus pCMV6). (B) KLF4 α /KLF4(FL) imbalance in MDA-MB-231 cells reduces KLF4(FL)-provoked p21^{Cip1} induction as evidenced by qPCR (left panel). Right panel shows the control using different KLF4(FL)/pCMV6 ratios. Data are expressed as the mean \pm SEM. $n = 3$. TBP: TATA-Box binding protein. * $p \leq 0.05$ (KLF4(FL) versus (FL)/ α 3:2). ** $p \leq 0.05$ (KLF4(FL) versus pCMV6). (C) MDA-MB-231 cells were transiently transfected with different ratios of KLF4 α and KLF4(FL) followed by immunoblot analysis using specific antibodies for E-Cadherin and p21^{Cip1}. Note that KLF4 α /KLF4(FL) imbalances are reflected on protein levels as assessed by anti-KLF4 (KLF4(FL)) and anti-myc (KLF4 α) and abrogate E-Cadherin and p21^{Cip1} inductions. GAPDH, glyceraldehyde-3-phosphate dehydrogenase. *background band.

KLF6-v1 in prostatic tumors [35]. To our knowledge, nothing is known yet about polymorphisms within crucial splice-site regions for the *KLF4* gene in tumors. Further studies are needed to address the important questions of KLF4 splicing deregulation in tumors.

KLF4 α expression was initially identified in pancreatic cancer [26]. In pancreatic cancer patients, high KLF4 α levels were associated with an aggressive tumor phenotype and poor survival. Pancreatic tumor models showed that KLF4 α over-expression resulted in larger tumors, due to increased cancer cell proliferation [26]. Our data on KLF4 α in breast cancer mostly confirms this study with some significant novel additions and relevant differences: (i) Compared to Wei et al. [26] our sequencing

analysis showed that MDA-MB-231 cells contain a KLF4 protein with nine additional N-terminal amino acids (MRQPPGESD) corresponding to the EMBL Nucleotide Sequence Database accession number HF546201. This N-terminal variance in KLF4 has recently been identified and characterized for the potential of reprogramming [39]. (ii) KLF4 α expression has been described in pancreatic and prostatic cancer only [25, 26]. We extended this expression analysis by screening a total of 25 human cancer cells from 11 different tissues and identified *KLF4 α* transcripts in 21 out of the 25 cell lines tested (84%). These results indicate that *KLF4 α* is widely expressed in human tumors and that our findings in breast cancer may have relevance in other tumors as well. (iii) While KLF4 α was

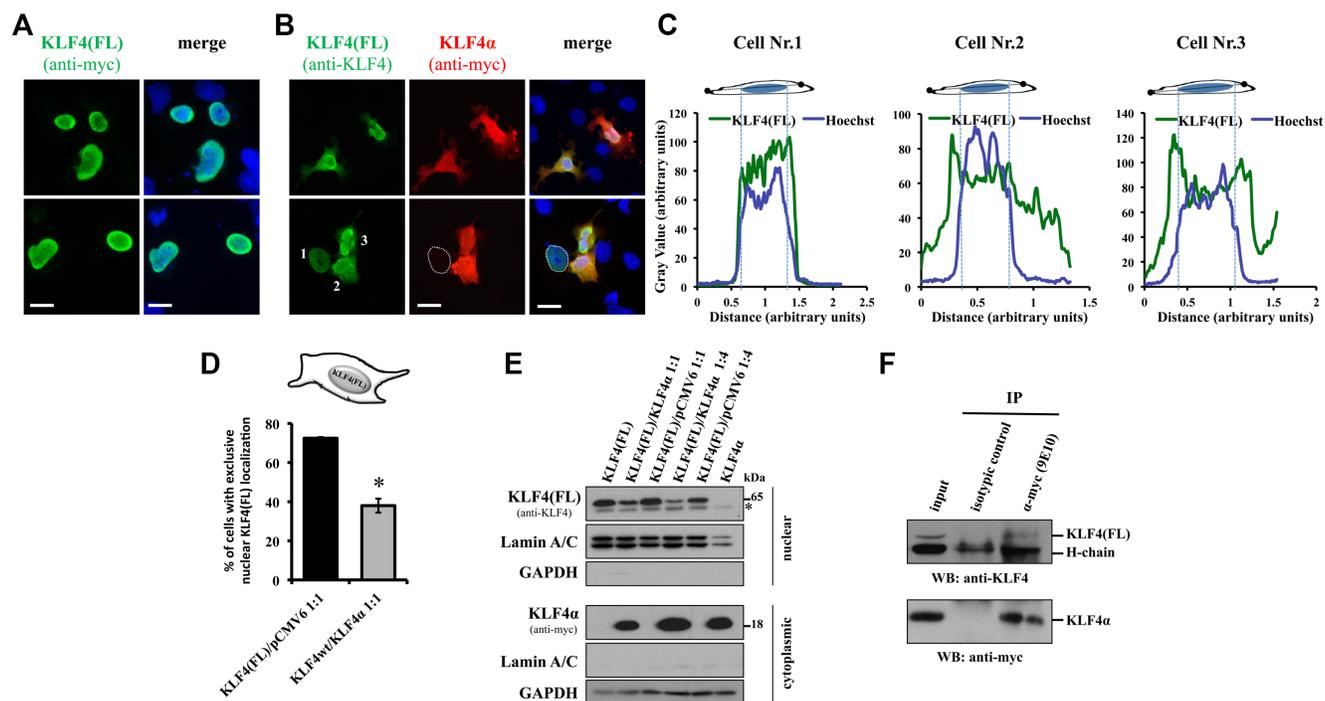

Figure 6: KLF4 α sequesters KLF4(FL) in the cytoplasm. (A) MDA-MB-231 cells co-transfected with a 1:1 mix of KLF4(FL)-myc and pCMV6, and stained 24 h after transfection. Two sample images are shown. KLF4(FL)-myc is mostly located in the nucleus overlapping with the Hoechst stain. scale bar: 20 μ m. (B) MDA-MB-231 cells transfected with a 1:1 mix of KLF4(FL) and KLF4 α -myc, and stained 24 h after transfection. Two sample images are shown. In KLF4 α -positive cells, KLF4(FL) is often localized in the cytoplasm. In the bottom row, the dotted line indicates a KLF4 α -negative cell that displays an exclusive nuclear staining for KLF4(FL). Hoechst staining to indicate the nuclei is shown in blue. scale bar: 20 μ m. (C) Linescan plots of the three cells in panel B, bottom are shown. Note, while in the absence of KLF4 α the linescan plots for KLF4(FL) (green line) and Hoechst (blue line) are almost identical (indicating strict nuclear KLF4(FL) expression in cell 1), presence of KLF4 α alters KLF4(FL) localization (cell 2 and 3). (D) Quantification of the co-transfection experiments. 100 KLF4 α -positive cells were analyzed for the exclusive nuclear localization of KLF4(FL) ($n = 3$). Graph shows difference of percentage of cells having strict nuclear KLF4(FL) expression in the KLF4(FL)/pCMV6 versus the KLF4(FL)/KLF4 α co-transfected cells. $*p \leq 0.05$ (KLF4(FL)/pCMV6 versus KLF4(FL)/KLF4 α). (E) Nuclear extracts of MDA-MB-231 cells co-transfected with different ratios of KLF4 α /KLF4(FL) analyzed by immunoblots. Note that altering the KLF4 α /KLF4(FL) ratio decreases nuclear KLF4(FL) levels compared to the respective ratios of KLF4(FL)/pCMV6. Nuclear extracts were defined by the presence of LaminA/C and the absence of GAPDH. GAPDH, glyceraldehyde-3-phosphate dehydrogenase. *background band. (F) Co-immunoprecipitation analysis of the association between KLF4 α and KLF4(FL) using total cell extracts of MDA-MB-231 cells transiently transfected with a 1:1 ratio KLF4 α -myc/KLF4(FL) 36 h after transfection. Total cell extract (input) was used as control in western blots. Immunoprecipitation with α -myc followed by western blot with α -KLF4 detects a specific band at 65kDa, which corresponds to KLF4(FL). Bottom panel shows that anti-myc (9E10) immunoprecipitated KLF4 α -myc successfully.

not expressed in normal pancreatic tissue [26], we clearly established *KLF4 α* expression in normal tissues. In our limited set of normal human tissues, *KLF4 α* was readily detectable in all of them (breast, kidney, lung, and ovary). (iv) *KLF4 α* expression was absent in normal pancreas, but correlated with tumor grade in pancreatic cancer patients [26]. We did not identify higher *KLF4 α* levels in kidney, lung, and ovarian cancer patients compared to their respective controls. A tendency towards increased *KLF4 α* levels compared to control was only observed in breast cancer patients. It is evident that larger sample numbers will be required to further clarify this point. However, we believe that not *KLF4 α* levels *per se* are important for its actions, but rather that the *KLF4 α* /*KLF4(FL)* ratio

determines whether *KLF4 α* can antagonize *KLF4(FL)* or whether *KLF4(FL)* can mediate its transcriptional gene regulation. Most of the tumor samples analyzed in this study displayed a significant increase of the *KLF4 α* /*KLF4(FL)* ratio compared to controls. Tumors can achieve this imbalance either by increased expression of *KLF4 α* , or by reduced levels of *KLF4(FL)*. Numerous studies report a loss of *KLF4(FL)* expression in tumors (e.g., [3]), suggesting that *KLF4(FL)* prevents tumor formation. However, it is reasonable to hypothesize that not the loss of *KLF4(FL)* *per se* is tumorigenic, but that a potential resulting increase of *KLF4 α* /*KLF4(FL)* ratio might stimulate tumor growth. Therefore, future studies should analyze *KLF4(FL)* as well as *KLF4 α* levels in cancer

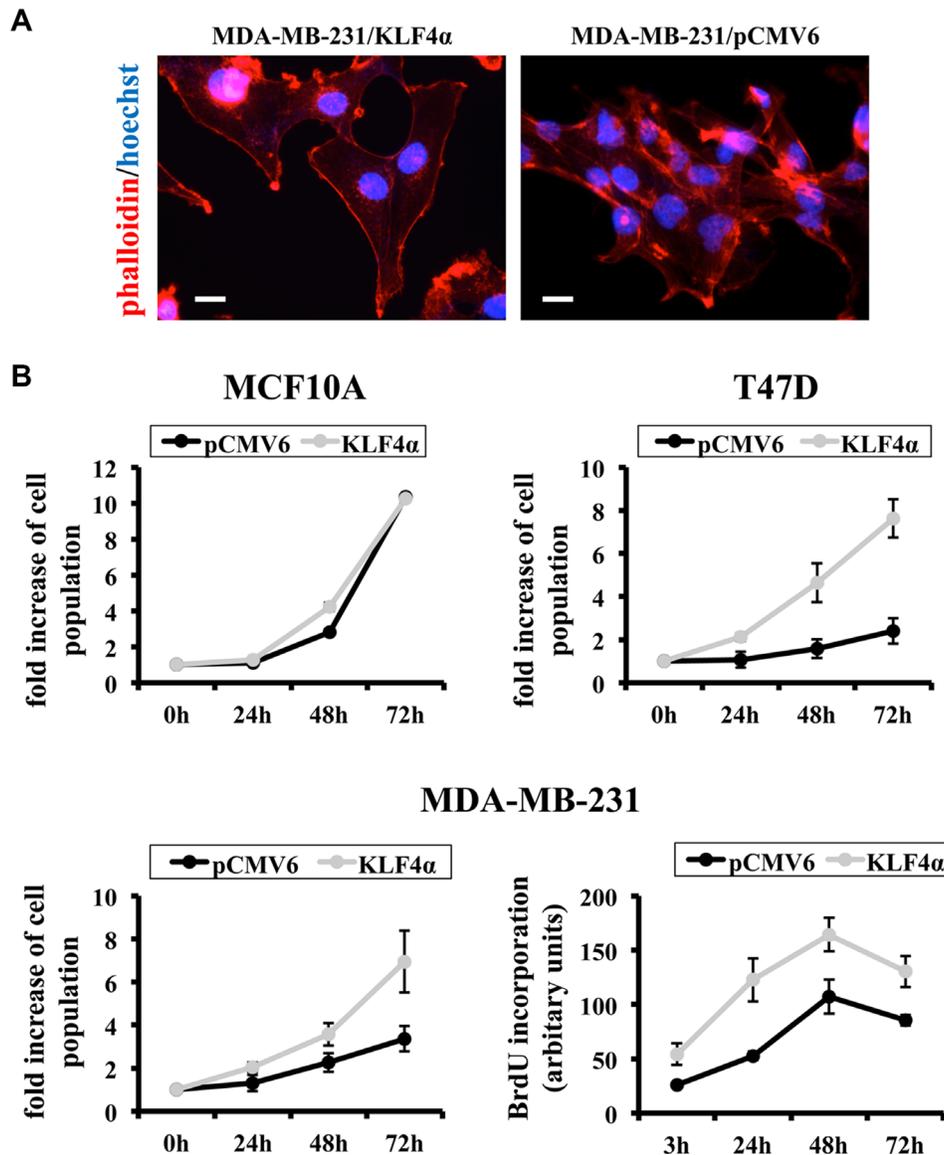

Figure 7: *KLF4 α* stimulates proliferation in MDA-MB-231 cells. (A) Forced over-expression of *KLF4 α* in MDA-MB-231 cells results in changes of the actin network as evidenced by phalloidin (red). Note the prominent cortical actin in *KLF4 α* expressing cells as compared to control. (B) While forced expression in the normal breast cell line MCF10A does not alter cell growth, it does stimulate proliferation in the breast cancer cell lines T47D and MDA-MB-231. Two different assays were used: Top and bottom left panels show the result of counting the cells after the indicated times. The bottom right panel displays BrdU incorporation. * $p \leq 0.05$ (*KLF4 α* versus pCMV6).

patients. (v) We used a cellular model which allowed us to specifically manipulate the KLF4 α /KLF4(FL) ratio and to follow the effects of altered KLF4 α /KLF4(FL) ratios on E-Cadherin and p21^{Cip1}. In transfected MDA-MB-231 cells, a KLF4 α /KLF4(FL) mix of 1:1 was sufficient to inhibit KLF4(FL)-mediated regulation of the transcriptional targets E-Cadherin and p21^{Cip1}. Importantly, these artificially generated KLF4 α /KLF4(FL) ratios are in the range of the ratios observed in tumor patients.

In summary, this is the first study on KLF4 α expression in breast cancer. We show that KLF4 α is expressed in various normal tissues, but that tumors display an increase of the KLF4 α /KLF4(FL) ratio compared to control. We demonstrate that although KLF4(FL) acts as a tumor-inhibiting gene in MDA-MB-231 cells, an increased KLF4 α /KLF4(FL) ratio is able to oppose this effect. KLF4 α interacts with KLF4(FL) in the cytoplasm, which prevents nuclear localization of KLF4(FL), thereby inhibiting KLF4(FL) tumor-suppressive functions in the nucleus, such as growth inhibition. These results warrant further studies on the role of KLF4 α in tumorigenesis using larger sets of clinical samples. Future studies should be aimed at analyzing whether targeted inhibition of KLF4 α suppresses breast cancer cell growth. Also, it will be interesting to see how KLF4 α /KLF4(FL) imbalance affects the cancer stem cell-like population, which plays an important role in tumor development and emergence of therapy-resistant clones in breast cancer. Finally, it has to be analyzed whether presence of KLF4 α , a KLF4 antagonist, might be an important, so far neglected player in the generation of induced pluripotent stem cells.

MATERIALS AND METHODS

Cell culture, transfection, stable cells

MDA-MB-231 were purchased from the American Cell Type Culture collection, and cultured according to the manufacturer's instructions under standard conditions. Supplementary Table S1 lists all cell lines used in this study.

For transfections, cells were split the day before so that they reached 60-70% confluence. Transfections were performed using JetPei (Polyplus, Illkirch-Graffenstaden, France) following their protocol with 1 μ g DNA and 2 μ l JetPei reagent per 35 mm dish. 5 h after transfection, the transfection mix was removed and cells were replenished with fresh medium. Cells were analyzed 24 - 48 h post-transfection.

For the generation of stable MDA-MB-231 cells, expression plasmids (backbone vector: pCMV6-A-Puro, Origene, Rockville, USA) containing a puromycin selection marker were used for transfection. 24 h after transfection, puromycin-selection was started (2 μ g/ml; Sigma-Aldrich, St. Louis, USA). Every other day, fresh medium including puromycin was added and selective pressure maintained

until the emergence of resistant cell clones. Stable cells were characterized by quantitative real-time PCR (qPCR), immunofluorescence, and immunoblotting.

For the over-expression experiments, pools of cells have been used and experiments have been repeated at least three times after independent transfections.

Cloning of the KLF4 constructs

cDNA was synthesized from total RNA extracted from MCF10A and MDA-MB-231 cells. PCR was performed on the cDNA's using Taq Polymerase (Roche, Rotkreuz, Switzerland) and the following primers: 5'-ATGAGGCAGCCACCTGGCGAG-3'/5'-CATCGGAGCGGGCGAATTTCC-3'. Amplicons were separated on agarose gels, purified using the QIAquick Gel Extraction kit (QIAGEN, Hilden, Germany) and then used for sequencing.

To generate a myc-tagged KLF4(FL) expression plasmid, the following primers were used: 5'-TGCGATCGCCATGAGGCAGCCACCTGGCGAGTCTG-3'/5'-ATA CGGTAATAATGCCTCTTCATGTGTAAGGC-3'. The primer set 5'-ATGCGATCGCCATGAGGCAGCCACCTGGCGAGTCTG-3'/5'-ATACGCGTGTTCATCTGAGCGGGCGAATTTCC-3' was used for cloning a myc-tagged KLF4 α expression construct. Primers contained an *AsiSI* (forward primer) and a *MluI* restriction sites (reverse primer), respectively. This allowed the directional cloning into the mammalian expression plasmid pCMV6-A-Puro (Origene) containing a myc tag. All expression plasmids were sequence-verified.

RNA extraction, cDNA synthesis, qPCR analysis

Total RNA was isolated from approximately 80% confluent cells using the RNeasy Mini Kit (QIAGEN). Total RNA was further purified by the Turbo DNase Treatment and Removal kit (ThermoFisher Scientific, Lucerne, Switzerland). cDNA was synthesized from 1 μ g total RNA using the High Capacity cDNA Reverse Transcription kit (ThermoFisher Scientific). mRNA levels were quantified by qPCR using Platinum SYBR Green qPCR SuperMix-UDG with ROX (Invitrogen) on an ABI StepONE Plus Instrument (40 cycles of 95°C for 15 s and 58°C for 30 s). Relative expression was calculated using the $\Delta\Delta C^T$ method, normalizing values to TATA-Box binding protein (TBP) within each sample; standard error of the mean (SEM) was calculated from the results of triplicates. All primers were tested for specificity and efficiency. Primers used are listed in Supplementary Table S2.

TissueScan Real-Time Arrays were obtained from Origene. qPCR analysis of the TissueScans was performed according to their manual.

Total RNA from human breast tissues (ductal carcinoma) and a matched pair RNA sample from breast tissue were purchased from Amsbio (Abingdon, UK).

Western blotting

Cell extracts were prepared in RIPA buffer as described [40]. Alternatively, cultures were rinsed with phosphate-buffered saline (PBS), drained, and lysed in reducing Laemmli sample buffer. After boiling the samples for 5 min at 95°C, proteins in Laemmli buffer were separated by SDS-PAGE under reducing conditions and blotted to polyvinyl-difluoride membranes (ThermoFisher Scientific). Then, membranes were stained with amido black to control for equal protein loading and blotting efficiency. After blocking for 1 h at room-temperature in Tris-buffered saline (TBS) containing 0.05% Tween and 5% skim milk powder (Sigma-Aldrich), membranes were incubated over-night with primary antibodies at 4°C. Membranes were washed three times in TBS-Tween and incubated for 1 h with peroxidase-conjugated anti-rabbit/mouse IgG at room temperature. Blots were developed using SuperSignal West Dura (ThermoFisher Scientific) and exposed to Super RX Fuji Medical X-Ray films (Fujifilm, Diesldorf, Switzerland).

Primary antibodies used: anti-myc (clone 9E10), anti-KLF4 (ab151733) and anti-GAPDH (ab9485, all from Abcam, Cambridge, UK), anti-LaminA/C (#612162, BD Biosciences, East Rutherford, USA), anti-E-Cadherin (#3195), anti-p21^{Cip1} (#2947), and anti-p27^{Kip1} (#3686, all from Cell Signaling Technologies, Danvers, USA). The KLF4 α -specific antibody GN330 [26] was a generous gift from Profs. Keping Xie and Daoyan Wei (MD Anderson Cancer Center, University of Texas, USA).

Some Western Blots were analyzed densitometrically using ImageJ software version 1.51a (NIH, Bethesda, MD; <http://rsbweb.nih.gov/ij>). Briefly, the total band intensity of the protein of interest was normalized to the GAPDH band intensity of the same extract in the same experiment.

Cytoplasmic and nuclear protein extraction

For preparation of cytoplasmic and nuclear cell extracts, cells grown in 10 cm dishes were washed in ice-cold PBS and lysed in lysis buffer (10 mM HEPES pH 7.9, 100 mM KCl, 1 mM EDTA, 1 mM DTT, 0.5% NP-40 and protease inhibitor cocktail (Roche)). After centrifugation, supernatants were collected as cytoplasmic fractions. Nuclear pellets were washed with lysis buffer lacking NP-40, and extracted with 250 mM Tris-HCl pH 7.8, 100 mM KCl, 1 mM EDTA, 1 M DTT, 0.5% NP-40, 20% glycerol shaking at 4°C for 1 h, followed by centrifugation to clarify the nuclear extracts. Proper fractionation was confirmed by GAPDH and LaminA/C presence as cytoplasmic and nuclear marker, respectively.

Co-immunoprecipitation

For co-immunoprecipitations (co-IP), cells grown in 10 cm dishes were lysed in ice-cold co-IP buffer (50 mM

Tris-HCl, pH 7.4, 1% Triton-X-100, 25 mM Hepes, 150 mM NaCl, 0.2% Sodium deoxycholate, 5 mM MgCl₂ and protease inhibitor cocktail Roche). Cell lysates were incubated for 60 min on a rotary wheel at 4°C. After centrifugation for 15 min at 13200 rpm, the supernatant was transferred into a new 1.5 ml tube and protein concentration measured by a Bradford Assay (Expedeon, Swavesey, UK). Equal amounts of cell lysates (200 μ g) were pre-cleared for 1 h at 4°C on a rotary wheel. Pre-cleared lysates were incubated with 3 μ g of anti-myc (9E10) antibody or 3 μ g of control mouse IgG (mAB002, R&D Systems, Minneapolis, USA) and incubated over-night at 4°C on a rotary wheel. Dynabeads Protein G (Life Technologies) were added to the immunocomplexes and incubated for 1 h at 4°C on a rotary wheel. After 3 washes with co-IP buffer, complexes were eluted in denaturing SDS sample buffer, resolved by SDS-PAGE and analyzed by immunoblotting

Immunofluorescence and quantification

For stainings, cells were grown in 35 mm dishes containing four separate wells (Greiner Bio-One, Frickenhausen, Germany). Cells were washed twice with PBS before fixation in 4% paraformaldehyde at room-temperature. Afterwards, cells were washed three times with PBS, permeabilized in 0.1% Triton-X-100 for 5 min and incubated with primary antibody for 2 h at room-temperature. After three PBS rinses, cells were incubated with fluorescent-labeled secondary antibodies (Molecular Probes) for 1 h in the dark, rinsed with PBS and coverslip-mounted with ProLong Gold antifade reagent (Molecular Probes). Hoechst was added to the last washing step. Cells were examined and photographed using an Axioskop microscope (Carl Zeiss MicroImaging, Oberkochen, Germany) connected to an ORCA-ER digital camera (Hamamatsu, Solothurn, Switzerland).

Linescan plots were performed using ImageJ software version 1.51a. Briefly, a line, spanning an entire cell, was drawn and the gray intensities along the line (through the cell) were plotted.

For quantification, 100 cells per experimental group were analyzed in triplicates. KLF4(FL) in KLF4 α -positive cells was categorized as “strictly nuclear” or “nuclear+cytoplasmic”. Quantification was blinded and performed by two lab members.

Cell growth

Cell growth was analyzed by two different methods. First, 9×10^4 cells were plated into 35 mm dishes in 1% FCS-containing medium. At the indicated time points, cells were trypsinized and counted. The increase in cell population was calculated as fold induction compared to the time-point 0. Second, the fraction of cells within S phase was determined using a 5-bromo-2'-deoxyuridine (BrdU) incorporation assay (Roche) as described in their manual.

Briefly, 5×10^3 cells were plated into black 96-well plates with clear, flat bottom (PerkinElmer, Waltham, USA) in 1% FCS-containing medium. Cells were allowed to proliferate for the indicated times before labeling with BrdU for 2 h at 37°C. Afterwards, cells were fixed for 30 min, and incubated with the anti-BrdU antibody conjugated with peroxidase for 90 min, followed by extensive washing. BrdU substrate was added and incubated for 3 min before measuring chemiluminescence signals using a Mithras LB940 luminometer (Berthold Technologies, Zug, Switzerland).

Statistical analysis

Data are represented as means and standard deviation/standard error of the mean (SD/SEM) as stated in the figure legends. Statistical analysis using a two-tailed *t*-test was carried out either at www.physics.csbsju.edu/stats/t-test.html or with the program GraphPadPrism Version 5. All experiments have been performed at least 3 times in triplicates. The difference between two data sets was statistically significant when $p \leq 0.05$.

ACKNOWLEDGMENTS

First and most importantly, I (MD) want to express my deepest gratitude to Ruth Chiquet-Ehrismann, who died on September 4, 2015. I am thankful for everything I have learned during my time in her lab, for her career support, her generosity, her advice and her belief in me. She will be missed enormously.

We thank Prof. Daoyan and Prof. Keping Xie (MD Anderson Cancer Center, University of Texas, USA) for providing aliquots of the anti-KLF4 α antibody (GN330), Ismaïl Hendaoui for his expert help in co-IP's and Profs. Richard P. Tucker, Nancy E. Hynes, Matthias Chiquet and Patrick Matthias for critical reading of the manuscript.

CONFLICTS OF INTEREST

No potential conflicts of interest were disclosed.

GRANT SUPPORT

R.C.-E. and M.D. received funds from the Swiss National Science Foundation grant number NF31003A_156740.
