ABSTRACT

Vulvar cancer is rare but incidence rates are increasing due to an aging population and higher frequencies of young women being affected. In locally advanced, metastatic or recurrent disease prognosis is poor and new treatment modalities are needed. Immune checkpoint blockade of the PD-1/PD-L1 pathway is one of the most important advancements in cancer therapy in the last years. The clinical relevance of PD-L1 expression in vulvar cancer, however, has not been studied so far. We determined PD-L1 expression, numbers of CD3[+] T cells, CD20[+] B cells, CD68[+] monocytes/macrophages, Foxp3[+] regulatory T cells and CD163[+] tumor-associated macrophages by immunohistochemistry in 103 patients. Correlation analysis with clinicopathological parameters was undertaken; the cause-specific outcome was modeled with competing risk analysis; multivariate Cox regression was used to determine independent predictors of survival. Membranous PD-L1 was expressed in a minority of tumors, defined by HPV-negativity. Its presence geographically correlated with immunocyte-rich regions of cancer islets and was an independent prognostic factor for poor outcome. Our data support the notion that vulvar cancer is an immunomodulatory tumor that harnesses the PD-1/PD-L1 pathway to induce tolerance. Accordingly, immunotherapeutic approaches might have the potential to improve outcome in patients with vulvar cancer and could complement conventional cancer treatment.

INTRODUCTION

Vulvar cancer - with squamous cell carcinoma (VSCC) being the predominant histologic subtype - is only the fourth most common tumor of the female genital tract, accounting for 5% of all gynecologic malignancies in developed countries [1]. However, overall incidence rates are increasing, mainly attributable to a strong rise in younger women [2–4]. Etiology divides VSCC into two subtypes: (i) human papillomavirus (HPV)-associated tumors, typically diagnosed in younger women; and (ii) tumors arising in the background of *lichen sclerosus et atrophicus*, mostly seen in advanced age [5]. Approximately 65% of VSCCs are HPV-positive and the oncogenic high-risk types HPV-16/-18/-31/-33 are most frequently detected [6]. However, the burden of VSCC still lies with older women, in whom survival rates are low due to more aggressive tumors, diagnosis at later stages and frequent under-treatment [7, 8]. Surgery - consisting of local tumor excision with sentinel or inguinofemoral lymph node dissection - is considered the cornerstone of therapy. It leads to an excellent 5-year survival rate of 86% in localized VSCC [9]. Patients with locally advanced, metastatic or recurrent disease are additionally treated with radio- and chemotherapy. But the outcome is still poor and new therapeutic options are needed to reduce mortality in these women [10].

The recent success of checkpoint blockade caused a paradigm shift in cancer treatment. It focuses on disinhibiting tumor-specific immune responses. One of the most important immune-inhibitory checkpoint pathways consists of (i) the programmed death 1 (PD-1) receptor, expressed on activated T cells; and (ii) the programmed death ligand 1 (PD-L1), expressed on tumor cells [11]. Their interaction negatively regulates T cell proliferation and function. This process allows the tumor to evade immune detection. PD-L1 levels were found to be present on various solid cancer types, typically conferring a poor prognosis [12–15]. Blockade of the PD-1/PD-L1 signaling pathway was demonstrated to enhance T cell function and has been successfully used in the treatment of multiple tumor types [16]. To bring attention to the opportunity checkpoint blockade might offer to VSCC, we here evaluate the clinical impact of PD-L1 expression. Our approach is motivated by two observations. First, VSCC is able to provoke a tumor-specific immune response. Both pro-inflammatory subsets and immunosuppressive mechanisms have been described [17–19]. Second, the clinical response to immune checkpoint blockade is correlated with tumor PD-L1 expression across multiple malignancies [20]. To form the basis for future use of checkpoint inhibitors in VSCC we here aim to analyze (i) the expression status of PD-L1; (ii) its relation to tumor biology; and (iii) its prognostic value.

RESULTS

VSCC is characterized by an immune-active tumor microenvironment

We first evaluated whether VSCC is a malignancy able to elicit an inflammatory response using samples that cover the wide range of the disease (Table 1). Several cellular components of the immune system were evaluated in cancer cell nests and the stroma separately. We found CD3$^+$ T cells, CD20$^+$ B cells and CD68$^+$ monocytes/macrophages to be present in both compartments (Table 2). Immunosuppressive cell populations analyzed included Foxp3$^+$ regulatory T cells (T_{reg} cells) and CD163$^+$ tumor-associated macrophages (TAMs), shown to play a crucial role in various cancer types [21, 22]. These anti-inflammatory cell types also existed in both the tumor and the stroma (Supplementary Table 1). For all immune cell types analyzed frequencies in the stroma predominated over numbers in tumor islets.

VSCC express PD-L1 at variable degrees of intensity

In the next step, we aimed to determine whether additional immune escape mechanisms of the tumor are present. Membranous expression of PD-L1 was identified in 23.3% (24/103) VSCC samples. The intensity of continuously stained cell membranes ranged from low (3 cases) to moderate (4 cases) to high (13 cases); four cases lacked confluence of staining (Figure 1A). The amount of stained cells varied between 5 and 60%; no positive case exhibited less than 5% of PD-L1 stained cells. To more closely reflect the biological reality we applied a stringent threshold. Using this cut-off, 9.7% (10/103) VSCCs were classified as PD-L1 positive (Table 2).

Immune activation is associated with PD-L1 expression in VSCC

To examine the relationship between tumor PD-L1 and the immune microenvironment, VSCCs were divided according to their level of immune checkpoint expression. Then, we correlated PD-L1 with the presence of immune cells. We found its expression to be significantly related with CD3$^+$, CD20$^+$ and CD68$^+$ intra-tumor immunocytes (Figure 1B). Numbers of CD3$^+$ T cells, CD20$^+$ B cells and CD68$^+$ monocytes/macrophages were always higher in PD-L1-positive VSCCs. Additionally, the amount of stromal CD68$^+$ monocytes/macrophages correlated proportionally with the intensity of tumor PD-L1 labeling. With regard to immunosuppressive cell populations, however, no correlation was observed between PD-L1 expression of the tumor and the amount of infiltrating T_{reg}

cells and TAMs, respectively (Supplementary Figure 1). This was true for immunocytes found in tumor islets and stroma.

PD-L1 expression is associated with HPV-negativity

In order to better understand PD-L1-related tumor biology, clinicopathological parameters were correlated with the presence of PD-L1 expression. However, no significant associations were observed between PD-L1 presence and typical clinicopathological factors (Table 3). Based on the two pathogenic pathways known for VSCC, we then asked whether PD-L1 expression enriches in one entity. We determined (i) p53 immunoreactivity and the proliferation marker Ki-67 to identify VSCCs arising in the setting of *lichen sclerosus et atrophicus* [23]; (ii) high risk HPV and p16INK4a (a marker of HPV-transforming activity) to identify VSCCs driven by viral infection [24]. We found PD-L1 expression to occur more often in high risk HPV-negative VSCCs (Table 4). This finding was confirmed by the observation that PD-L1 positivity also correlated with the absence of p16INK4a. With the exception of PD-L1, no difference was found for immune cells between viral and non-viral etiology (Figure 2).

PD-L1 expression predicts impaired survival in VSCC

Given our observation that PD-L1 correlates with non-HPV pathogenesis, we analyzed whether the presence of PD-L1 would be of use to prognosticate poor outcome in VSCC. Since our cohort had an average age of 64 years, in which deaths from non-cancer illnesses are expected to occur in a higher proportion, the effect of mortality from causes other than VSCC was
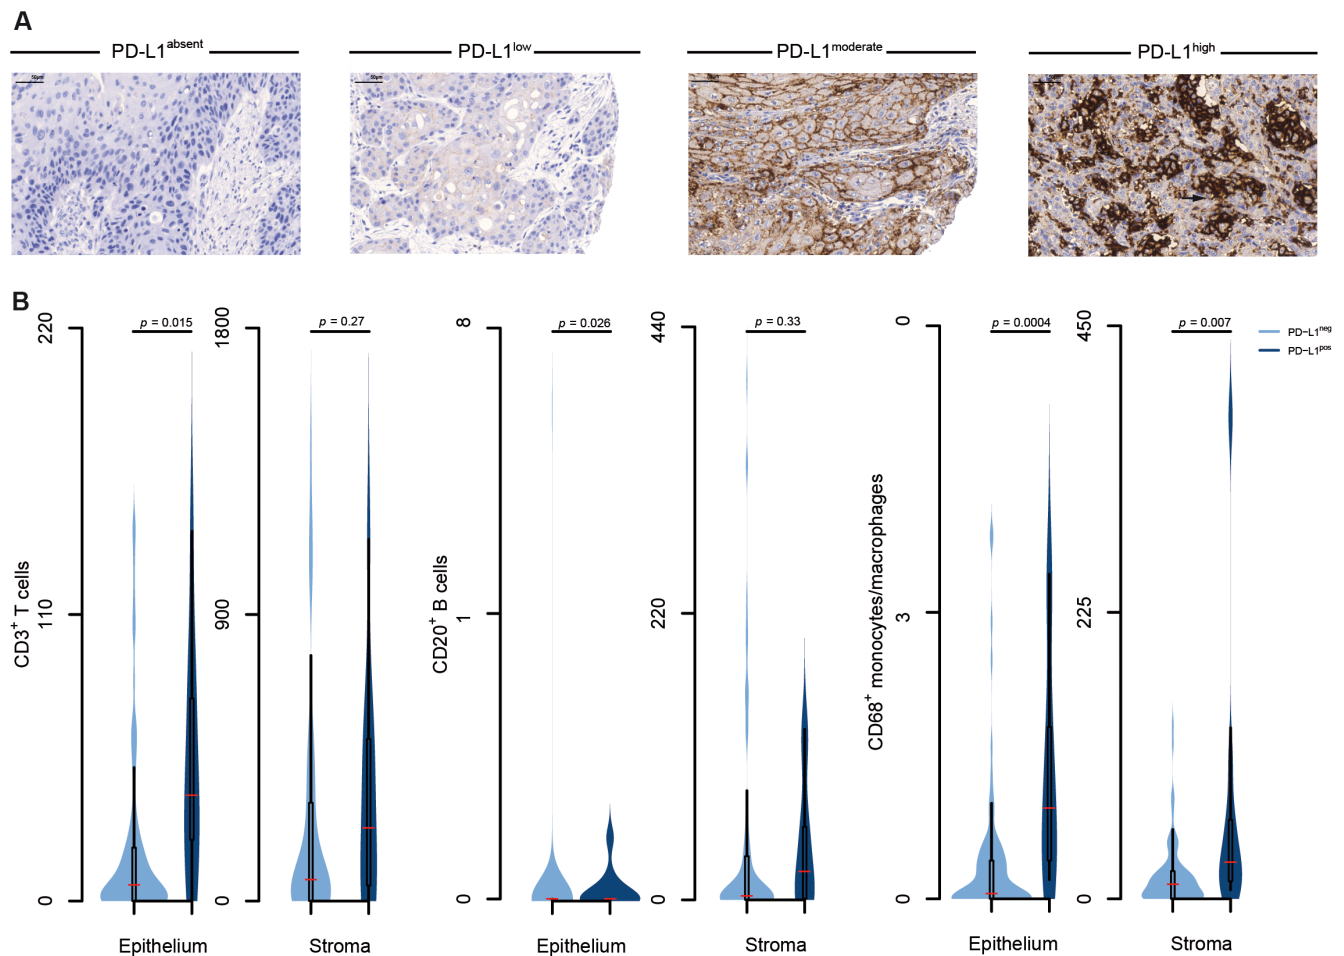

Figure 1: Identification of an immune microenvironment in VSCC. (A) Representative images depict various expression levels of membranous PD-L1 expression in VSCC (brown cell membrane, arrow) visualized by immunohistochemistry; hematoxylin (blue) was used for nuclear staining (bright field image, 300× magnification). **(B)** Expression of PD-L1 was determined by immunohistochemistry in 103 patients with VSCC; immune cell populations were enumerated in the tumor (epithelial) and the peri-tumoral micromilieu (stroma) using immunohistochemistry; samples were divided into absent and present PD-L1 expression groups; frequencies of immune cells were calculated and plotted as number of cells per stromal and epithelial fraction, respectively, of the TMA; violin plots show the distribution of data points; the median, 25th and 75th percentiles and whiskers are depicted.

Table 3: PD-L1 expression does not correlate with clincopathological parameters

modeled as competing risk. PD-L1 expression was able to discriminate between recurrence-free survival (RFS) rates relating a positive staining to a significantly more unfavorable outcome (Figure 3A). Additionally, PD-L1 expression tended to be associated with a shorter cancer-specific survival (CSS, Figure 3B). We used Cox regression analysis and found the presence of PD-L1 also to be an independent prognostic factor for RFS (Table 5). Lymph node involvement is known to be the most important predictor of disease outcome and was used as the gold standard in our analysis [25–27]. Of note, PD-L1 expression enhanced the risk of relapse by 3.029 times, a hazard ratio (HR) comparable to that of lymphatic metastasis.
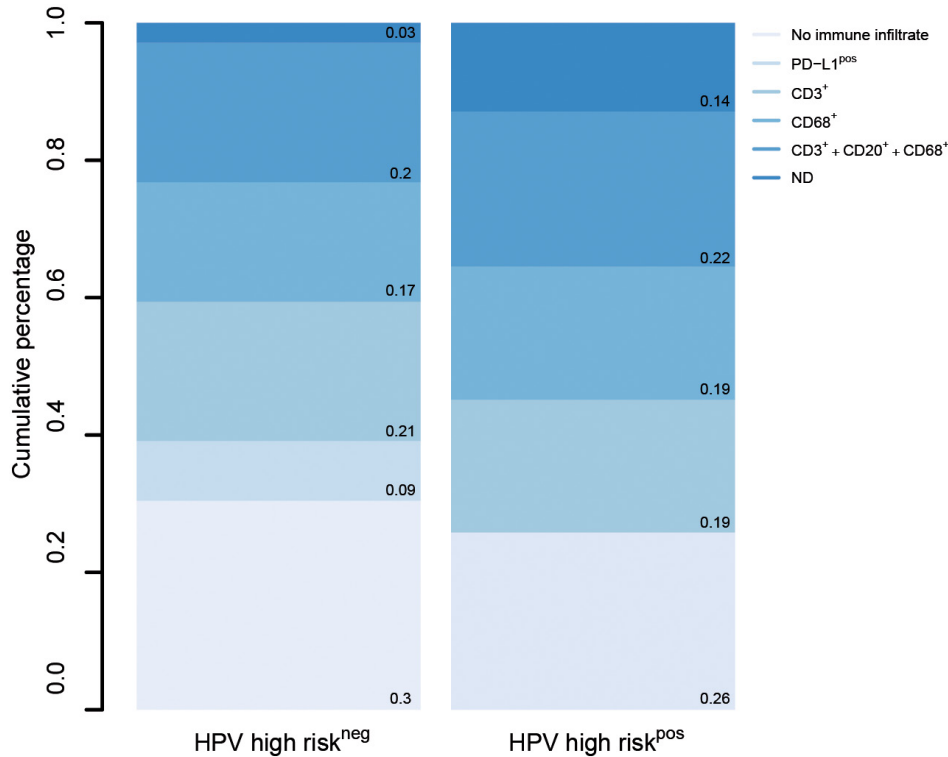

Figure 2: PD-L1 expression differs between HPV-positive and -negative cases. Tumors were grouped according to HPV-status; stacked bar graphs illustrate relative proportions of immune parameters as determined by immunohistochemistry (immunocytes in the presence of PD-L1, infiltration of CD3+ or CD68+ cells only, concurrent immune infiltration of multiple immune cell types).
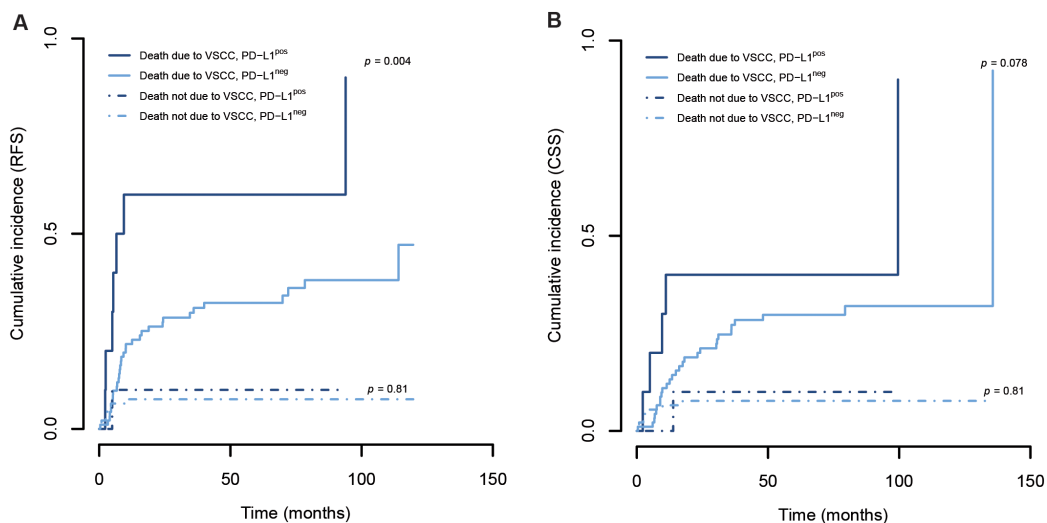

Figure 3: PD-L1 expression is a prognostic factor in VSCC. The membranous expression of PD-L1 in cancer cells was determined by immunohistochemistry; cumulative incidence analysis was performed using competing risk regression (death from VSCC was the main event and death from other causes the competing risk approach); results of Gray's test are provided.

Table 5: Risk factors affecting recurrence-free and overall survival

| Variable | Recurrence-free survival | | | | | |
| | Univariate analysis | | | Multivariate analysis[*] | | |
	HR	95% CI	*p*-value	HR	95% CI	*p*-value
PD-L1 immunoreactivity (positive vs. negative)	3.125	1.448 - 6.745	0.0037	3.029	1.228 - 7.471	0.0018

DISCUSSION

While immune checkpoint blockade may offer a promising novel therapeutic approach with regard to locally advanced, metastatic or recurrent disease, little is published about the immune landscape in VSCC and no data are available on the clinical relevance of PD-L1. We found PD-L1 to be expressed in VSCC within an immune-rich environment. The correlation of PD-L1 with HPV-negativity and poor outcome points towards immune escape mechanisms in a distinct subset of VSCC.

We observed CD3[+] T cells, CD20[+] B cells and CD68[+] monocytes/macrophages as well as Foxp3[+] T_{reg} cells and CD163[+] TAMs to be present in peri- and intra-tumor areas. Data on the role that the immune system plays in VSCC are still scarce and conflicting. In accordance with our results, earlier studies have discovered evidence of CD4[+] and CD8[+] T cells in cancer nests and the peri-tumoral stroma [17–19]. However, their association with the clinical behavior of VSCC has remained largely unclear. A higher number of cytotoxic CD8[+] T cells did not correlate with better outcome suggesting counteracting inhibitory mechanisms. In accordance with this hypothesis, higher levels of indoleamine 2,3-dioxygenase (IDO) expression were shown to be associated with poor outcome [28]. These findings, however, could not be replicated in a second study [18].

Our findings point towards a vital role of PD-L1 in the immune escape of VSCC. The observed correlation between tumor-associated immune cells and PD-L1 expression suggests that the VSCC-directed immune response provokes tolerance. The more stringent association with immunocytes in cancer cell islets is in accordance with previous data showing that intra-tumor leukocytes reflect immune reactions against cancer with higher accuracy [22]. Of note, a high density of CD8[+] T cells at the tumor site itself was shown to be crucial for treatment response to PD-L1 blockade [29, 30]. The extensive occurrence of intra-tumor T cells in VSCC might thus recommend immune checkpoint blockade as a powerful therapeutic tool. In contrast to previous data, we failed to identify a significant relationship between immunosuppressive cell populations and PD-L1 expression in VSCC. PD-L1 has been shown to maintain the survival and to increase the suppressive activity of inducible T_{reg} cells [31]. Similarly, PD-L1 expression was observed to positively correlate with the amount of CD163[+] TAMs in melanoma [32]. Potential reasons for divergent findings include inadequate VSCC sample size given the low expression of PD-L1, tumor site heterogeneity not represented by TMAs and the use of distinct antibodies.

Overall, we found PD-L1 to be present in VSCC, albeit at a low frequency. A previous study evaluated PD-L1 in a small number of 23 VSCCs [33]. However, the positivity rate was slightly higher (47.83%) when applying our threshold to their raw data. One reason for this conflicting result might be the use of a different antibody (9A11), which recognizes an epitope in the cytoplasmic domain of PD-L1, while our antibody targets an extracellular region [34, 35]. Authors also showed copy number gain of PD-1 ligands-encoding genes to occur commonly in VSCC. Unfortunately, their study lacked the evaluation of PD-L1-dependent clinical consequences.

We observed an unfavorable outcome in women with PD-L1-expressing tumors, suggesting impaired T cell-mediated immune responses and a microenvironment more permissive to tumor recurrence. Further support for this hypothesis comes from the observation that PD-L1 expression did not correlate with any commonly recognized feature of greater malignant potential. Our data suggest that PD-L1-based immune evasion mechanisms occur primarily in HPV-negative VSCCs. In penile cancer, PD-L1 expression was also found to be mainly expressed in HPV-negative tumors [36]. In Epstein-Barr-positive lymphoproliferative disorders and cervical cancer, however, viral infection represents a mechanism to provoke PD-L1 expression [37, 38]. In head and neck tumors conflicting results were published with regard to the HPV-dependence of PD-L1 [39, 40]. Thus, additional functional studies are needed to clarify the role HPV plays in PD-L1 induction.

Immune checkpoint blockade has been a game-changer in the field of tumor treatment and the identification of a biomarker that predicts the response to PD-L1 inhibition is essential. While PD-L1-negative tumors might also benefit from checkpoint inhibitors and some PD-L1-positive tumors do not respond to treatment, an increased probability of therapeutic response has been observed in tumors defined by the presence of PD-L1 [41, 42]. Accordingly, our observation of PD-L1 expression in the tumor bed of VSCC could be valuable in guiding clinical decision making. Additionally, our data suggest that the HPV status could potentially stratify patients for trials with anti-PD-L1 treatment.

To the best of our knowledge, this is the first study analyzing the clinical impact of PD-L1 expression in VSCC. The strength of our analysis lies in the compilation of immunological markers and diverse clinical as well as pathological data. A potential limitation of our study is the utilization of TMA. Although reliable for the determination of antigen expression, a heterogeneous protein distribution could potentially influence results [43]. In cervical squamous cell cancer, a tumor comparable to VSCC, both diffuse and focal expression of PD-L1 was observed [44]. Interestingly, women with homogeneously PD-L1-stained cervical malignancies showed poorer survival than those with a heterogeneous labeling. In the light of these data, we cannot rule out a TMA-dependent selection bias that favored diffuse PD-L1 expression. Our multivariate analysis identified PD-L1 expression as an independent prognostic factor of RFS but not of OS. Despite having a long-term follow-up, it may have been too short to identify independent prognostic factors of OS. Survival rates could have been influenced by (i) the study population with a high number of early stages; and (ii) therapy with curative intent in recurrent cases.

In summary, our study provides evidence that inhibitory pathways are operational in VSCC, arresting the tumor-specific immune response and influencing outcome.

Our findings will hopefully boost the development of immunotherapy in VSCC. While further efforts must be made to validate our findings of PD-L1 as a prognostic factor and determine its value as a predictive biomarker, checkpoint blockade could be the leading path to increased treatment success in VSCC.

MATERIALS AND METHODS

Patients and specimens

The retrospective study population included 103 patients with primary VSCC diagnosed at the University of Bonn between 2002 and 2013. Women who underwent neoadjuvant treatment were excluded. Patients were treated according to the S2k guideline of the German Cancer Society and the German Society for Gynecology and Obstetrics. Our cohort had a high number of women not treated with lymph node dissection. Due to cardiovascular comorbidities, 20 patients with early-stage tumors (pTIb/II) did not undergo lymphonodectomy; clinically and sonographically lymph nodes appeared to be unaffected. Additionally, the presence of lymphovascular space invasion was recorded, known to be a risk factor for lymph node metastasis [45]. In our cohort, however, no significant association between lymph node involvement and lymphovascular space invasion was noted, likely due to the fact that the detection is challenging in the absence of lymphatic endothelium-specific markers [46]. Baseline characteristics were obtained from a clinical database. Follow-up data were updated until August 2016. Histopathological diagnosis was made based on World Health Organization (WHO) criteria. The 2010 revision of the International Federation of Gynecology and Obstetrics (FIGO) system was used to assign the tumor grade; the 7th TNM classification of the Union for International Cancer Control (UICC) was used to determine the tumor stage. For tumors diagnosed before 2009, stages were re-classified according to the updated version. The study was approved by the Institutional Review Board of the Medical Faculty of the University of Bonn, Germany (228/15).

Tissue microarray (TMA) construction

The TMA was created from archival formalin-fixed paraffin-embedded tissue (FFPE) specimens. Sections stained with hematoxylin and eosin (HE) were used to identify representative tumor areas. For each case, one 1 mm core biopsy (0.785mm^2) was taken from the selected cancer nests and arranged in TMA blocks.

Immunohistochemistry

Immunostaining of PD-L1, CD3, CD20 and CD68 was performed on TMAs using an automated staining system (BenchMark ULTRA; Ventana Medical

Systems, Tucson, Arizona, USA) and the Ventana amplifier detection kit for visualization. Additionally, in a subset of our cohort (42 samples) staining of CD163 and Foxp3 was performed on serial 4μm sections using an automated staining system (DAKO TechMate 500; DAKO, Glostrup, Denmark) and the streptavidin-biotin-peroxidase/DAB technique (DAKO) for visualization. To determine PD-L1 expression we employed an antibody that is FDA-approved for selecting non-small cell lung cancer patients for treatment with the anti-PD-1 antibody pembrolizumab [35]. Primary antibodies included the following: mouse anti-human PD-L1 IgG1 monoclonal antibody (clone 22C3, dilution1:25; Dako, Glostrup, Denmark), mouse anti-human Ki-67 IgG1 monoclonal antibody (clone MIB-1, dilution 1:500; Dako), mouse anti-human p53 IgG2b monoclonal antibody (clone DQ-7, dilution 1:500; Dako), CINtec© Histology kit for the evaluation of p16^{INK4a} (Roche, Basel, Switzerland), mouse anti-human CD3 IgG2a monoclonal antibody (clone PS1, dilution 1:50; Novocastra, Newcastle Upon Tyne, United Kingdom), mouse anti-human CD20 IgG2a monoclonal antibody (clone L26, dilution 1:2000; Dako), mouse anti-human CD68 IgG3 monoclonal antibody (clone PG-M1, dilution 1:250, Dako), mouse anti-human CD163 IgG1 monoclonal antibody (clone 10D6, dilution 1: 1250, Leica Biosystems, Wetzlar, Germany), mouse anti-human Foxp3 IgG1 monoclonal antibody (clone 236A/E7, dilution 1: 50, Abcam, Cambridge, UK).

Evaluation of immunoreactions

Immunostained cells were analyzed with a Leica DM LB2 microscope (Leica Microsystems, Wetzlar, Germany) with the Pannoramic Viewer (3DHISTECH Ltd., Budapest, Hungary) or the Axio Observer D1 microscope (Zeiss, Jena, Germany) with the AxioVision 4.7 software (Zeiss). As a negative control for PD-L1 staining, we used sections of kidney, as a positive control sections of tonsil (Supplementary Figure 2). The membranous expression of PD-L1 on tumor cells was scored positive only if the immunoreactivity showed a honeycomb pattern (i.e. continuously stained cell membranes); cytoplasmic staining of PD-L1 was disregarded. Our analysis is based on an integrated proportion score that aims to harmonize different PD-L1 immunoassays [47]. In detail, a four-tier scoring system was applied to categorize the staining intensity (0, no staining; 1, low staining; 2, moderate staining; 3, high staining). Additionally, the percentage of PD-L1-stained tumor cells was estimated (0, <1%; 1, ≥1%; 2 ≥5%; 3, ≥10%; 4, ≥25%; 5, ≥50%). Malignancies with a staining intensity ≥ 2 in ≥ 5% of tumor cells were regarded as PD-L1 positive [48]. For Ki-67, a nuclear staining of cancer cells was interpreted as positive and the percentage of labeled cells in the vulvar epithelium was recorded; for p53, a nuclear staining in >25% of tumor cells was graded positive [49, 50]; for p16^{INK4a}, a continuous

strong nuclear plus cytoplasmic labeling of the basal cells with extension upward involving ≥30% of the epithelial thickness was regarded as positive [49, 51, 52]. Immune cell populations were determined separately in the epithelium and the stroma. T cells were identified by membranous and cytoplasmic expression of CD3, B cells by membranous and cytoplasmic expression of CD20, monocytes/macrophages by cytoplasmic expression of CD68, TAMs by membranous and cytoplasmic expression of CD163, T$_{reg}$ cells by nuclear staining of Foxp3. CD3$^+$ T cells, CD20$^+$ B cells and CD68$^+$ monocytes/macrophages were enumerated using the whole core area of the TMA (values are given as the number of immune cells per stromal and epithelial fraction of the TMA, respectively). T$_{reg}$ cells and TAMs were determined in three high-power fields (HPFs) with maximum infiltration and set in relation to the relative amount of tumor and stroma of these HPFs (values are given as the mean percentage of immune cells per stromal and epithelial fraction of individual HPFs). T$_{reg}$ cells were enumerated; TAMs were recorded digitally using a semi-automated computerized method as described before [21].

DNA extraction

After deparaffinization, tumor tissue was macrodissected from unstained slides and tissue was lysed with proteinase K overnight. Subsequently, extraction of DNA from FFPE-embedded tissue DNA was carried out with the BioRobot M48 Robotic Workstation and the corresponding MagAttract DNA Mini M48 Kit (Qiagen, Hilden, Germany) following the manufacturer's protocol. Quality of genomic DNA was assessed by agarose gel electrophoresis. DNA concentration of each sample was determined using Nanodrop 2000 (PeqLab, Erlangen, Germany).

HPV analysis

The HPV Type 3.5 LCD-Array Kit was used for the determination of HPV subtypes by hybridization to HPV-specific DNA probes (Chipron, Berlin, Germany). Amplification of HPV-specific DNA segments (L1 region) was achieved using the primer sets HPV '125' and HPV MY09/MY11. Ten microliters of the amplification products were hybridized to HPV type-specific capture probes fixed to an LCD array chip. All steps were performed according to manufacturer's recommendations.

Statistical analysis

Statistical analysis was carried out using 'R' version 3.2.3 (The R Foundation for Statistical Computing, Vienna, Austria). Comparisons between PD-L1 expression and continuous data were performed using the Kruskal-Wallis test; comparisons between PD-L1 expression (positive, negative) and categorical variables using the Fisher's exact test. Ki-67 staining in

≥ 30% of the epithelium was used as a cut-off point to assign tumors into high and low reactivity groups [23]. Poor-differentiation - grades 2,3 [53] - and advanced tumor stages - stages pT2, 3 [54] - have been shown to result in a poorer prognosis and, thus, thresholds were set between grades 2,3 and 1 and between stages pT2, 3 and pT1, respectively. Cumulative incidence analysis (RFS, CSS) was modeled using the competing risk approach and curves were compared with Gray's test [55]. Multivariate survival analysis (RFS, OS) was done using the Cox's proportional hazard regression model. The confidence interval for the median follow-up time was calculated using quantiles of the binomial distribution.

Abbreviations

VSCC, squamous cell carcinoma; HPV, human papillomavirus; PD-1, programmed death 1 receptor; PD-L1, programmed death ligand 1; IDO, indoleamine 2,3-dioxygenase; HR, hazard ratio; RFS, recurrence-free survival; CSS, cancer-specific survival; OS, overall survival; FFPE, formalin-fixed paraffin-embedded tissue; HE, hematoxylin and eosin; TMA, tissue microarray; TAM, tumor-associated macrophage; HPF, high-power field; T_{reg} cell, regulatory T cell; WHO, World Health Organization criteria; FIGO, International Federation of Gynecology and Obstetrics; UICC, Union for International Cancer Control.
